## How to use Fast Step Graph

Juan G. Colonna\* Marcelo Ruiz<sup>†</sup>

To install the last version of this package directly from GitHub uncomment and run:

```
# library(devtools)
# use "quiet = FALSE" if you want to see the outputs of this command
# devtools::install_github("juancolonna/FastStepGraph", quiet = TRUE, force = TRUE)

# Then, load it:
library(FastStepGraph)

# If you directly cloned the github repository,
# then you should uncomment these lines to load the functions:
# source('FastStepGraph.R')
# source('SigmaAR.R')
```

Simulate Gaussian Data with an Autoregressive (AR) Model:

```
set.seed(1234567)
phi <- 0.4
p <- 50  # number of variables (dimension)
n <- 30  # number of samples

# Generate Data from a Gaussian distribution
data <- FastStepGraph::SigmaAR(n, p, phi)</pre>
```

Afterwards, fit the Omega matrix by calling the Fast Step Graph function, like:

```
t0 <- Sys.time() # INITIAL TIME
G <- FastStepGraph::FastStepGraph(data$X, alpha_f = 0.22, alpha_b = 0.14)
difftime(Sys.time(), t0, units = "secs")
#> Time difference of 0.08510923 secs
# print(G$Omega)
```

If the nei.max argument is omitted, it will be 5. If you don't know the alpha\_f and alpha\_b values, the use cross-validation. To find the optimal  $\alpha_f$  and  $\alpha_b$  parameters for the previously generated X data, we can perform a cross-validation on a combination grid as follows:

```
t0 <- Sys.time() # INITIAL TIME
res <- FastStepGraph::cv.FastStepGraph(data$X, data_shuffle = FALSE)
difftime(Sys.time(), t0, units = "secs")
#> Time difference of 4.762491 secs
# print(res$alpha_f_opt)
# print(res$alpha_b_opt)
# print(res$0mega)
```

The arguments n\_folds = 5, alpha\_f\_min = 0.1, alpha\_f\_max = 0.9, n\_alpha = 32 (size of the grid search) and nei.max = 5, have defaults values and can be omitted. Note that, cv.FastStepGraph(X) is not an exhaustive grid search over  $\alpha_f$  and  $\alpha_b$ . This is a heuristic that always sets  $\alpha_b = \frac{\alpha_f}{2}$ . It is recommended to shuffle the rows of X before running cross-validation. The default value is data\_shuffle = TRUE, but if you want to disable row shuffle, set it to data\_shuffle = FALSE.

To increase time performance, you can run cv.FastStepGraph(X, parallel = TRUE) in parallel. Before, you'll need to install and register a parallel backend. Since Windows does not support forking, the same backend that works in a Linux or OS X environment will not work in Windows. To run on a Linux system the doParallel dependency must be installed install.packages("doParallel"). To run on a Windows system, doSNOW is used install.packages("doSNOW"). These parallel packages will also require the following dependencies: foreach, iterators and parallel. Make sure you satisfy them. Then, call the method setting the parameter parallel = TRUE, as follows:

```
t0 <- Sys.time() # INITIAL TIME
# use 'n_cores = NULL' to set the maximum number of cores minus one on your machine
res <- FastStepGraph::cv.FastStepGraph(data$X, parallel = TRUE, n_cores = 2)
difftime(Sys.time(), t0, units = "secs")
#> Time difference of 2.633945 secs
# print(res$alpha_f_opt)
# print(res$alpha_b_opt)
# print(res$0mega)
```

Remember, you can set the n\_cores parameter to a value equal to the number of cores you have, but be careful as this may freeze your system. Setting it to 1 disables parallel processing, and setting it to a number greater than the number of available cores does not improve efficiency.
